

Document Intelligence for Multi-Column Layouts

Figure 1: A representative system diagram.

Introduction. Many real documents are laid out in two columns: academic papers, newspapers, and reports. A faithful translation must preserve the reading order and keep figures and tables in place, while letting the translated text expand naturally. A rigid per-block layout makes the columns collide when the target language is longer. This example shows a clean reflow.

Method. The system detects a multi-column layout and reflows the translated text into one readable stream, preserving the figure above and keeping each paragraph's order.

Results. Translated output stays legible across languages, including those that expand significantly relative to English. Figures and captions stay anchored.

Conclusion. Detecting the column structure and choosing the rendering strategy automatically gives a readable result with no manual configuration. This document is synthetic and released into the public domain as a demonstration sample.
